Introduction

I am from Balochistan, Pakistan. When I moved to London for my MSc, people often asked me the same questions: Is Pakistan safe? Is it all desert? Do women have rights there? At first, I explained patiently, but after answering so many times, I wanted a better solution. That led me to create a chatbot to answer these questions and help educate others about my background. This is how Atlas Speaks began.

The idea really clicked when we learned about ELIZA in class. I realized that conversational interfaces could be more than just customer service tools; they could also serve as platforms for sharing culture, challenging stereotypes, and promoting inclusion by making diverse perspectives accessible to a broader audience. Therefore, I decided to build a chatbot that would not only share facts about Pakistan and debunk common myths, but also recommend Pakistani music, thereby making cultural knowledge more accessible to users from different backgrounds. My intention was for the chatbot to feel like talking to a wise old storyteller—someone who shares not only facts but also thoughtful reflections that encourage a more profound understanding and inclusivity.

The final chatbot uses three NLP techniques from our course: regex pattern-matching from Week 4 to detect myths, keyword classification from Week 6 for music recommendations, and the Gemini API from Week 8 to answer general questions. Getting to this point was not easy. I first tried TF-IDF, and my early chatbot was simple. My dataset for sharing facts, busting myths, and comparing cultures used trigger words to give a fact, a reflection, and a poem. Up until week 7, I was making progress. When we learned about LLM integration, especially SmolLM, I tried adding it to my chatbot. The results were unexpected. For example, when asked 'Is Pakistan a safe country?', it would reply 'no, no, no, no.' After starting over and using Gemini's API, I got the results I wanted. This essay explains what I built, what went wrong, and what I learned.

Background

When I started researching for this project, I came across work by Caldarini, Jaf and McGarry, 2022, who surveyed recent advances in chatbots. Their discussion of how chatbots utilize Natural Language Processing and Machine Learning, as well as the challenges and limitations inherent in these methods, directly informed my approach to the technical design. By understanding both the potential and constraints highlighted in their survey, I was able to make more informed decisions about which NLP techniques to implement and anticipate possible obstacles during development.

I also read about bias in language models, which became very relevant when SmolLM failed. Nangia *et al.*, 2020 created the CrowS-Pairs dataset to measure social biases in masked language models and found that widely-used models favor stereotypical sentences. Khandelwal *et al.*, 2024 found that LLMs show strong stereotypical bias, especially in non-Western contexts like India, with caste and religion biases that are different from Western biases. This explained why my SmolLM fine-tuning did not work; the model had already learned stereotypes about Pakistan from its pre-training data that my small dataset could not override.

For the conversational design, I looked at Wei *et al.*, 2024 who explored using LLMs for chatbots that collect user data through natural conversations. They tested different prompt designs and found that prompt structure significantly influences conversation flow. This helped me design the prompt for my Gemini API integration.

Implementation details

I started this project right after Week 5. My first step was to collect data using online articles, ChatGPT Deep Research, and Claude's Extending Thinking & Research. When designing my dataset, I made sure to include a wide range of regions and perspectives so that users from different backgrounds could find information that interested them or corrected their misconceptions. I created two JSON files. The first, atlas_myths_facts_comparisons.json, has 205 cultural facts from Balochistan, Punjab, Sindh, KPK, Gilgit-Baltistan, Azad Kashmir, Islamabad, and for comparison, the UK, USA, India, China, and Turkey. Each entry lists the region, trigger words to detect user intent, factual information, and a poetic reflection. The reflection uses storytelling traditions to encourage users to think more deeply about the content, not just read facts.

The second dataset, pakistani_music_database.json, includes 82 Pakistani songs from the 1980s to 2025. Each song entry has details like artist, year, mood, style, vocal intensity, tempo, genre, and language. I also added a 'why you will love it" field with personal recommendations. The idea was for users to tell the chatbot their mood and get song suggestions that match.

The chatbot is a Python class that inherits from ChatbotBase. When a user types something, it checks for basic commands like 'exit' or 'menu' first. If the user is in music mode, it runs the questionnaire. Next, it looks for myths using regex, then checks for comparison questions, and then sends the input to the Gemini API. If nothing matches, it shows a helpful message.

For myth detection using regex, each fact in my database has trigger phrases. If someone says "Balochistan is all desert" or "nothing but sand", these patterns match and respond with a fact about Balochistan's ancient Ziarat juniper forests with 5,000-year-old trees, plus the poetic reflection. Early on, I had a bug where I put 'return None' inside the for loop instead of outside, so it only checked the first fact and stopped. After fixing the indentation, it worked as intended.

One of the core features is detecting when users want to compare countries. I developed four regex patterns to handle this because people phrase comparison questions in different ways.

python

```
r'compare\s+(.+?)\s+(?:with|and|to|versus|vs)\s+(.+)',
                r'difference\s+between\s+(.+?)\s+and\s+(.+)',
```

```
r'(.+?)\s+versus\s+(.+)',
r'(.+?)\s+vs\s+(.+)'
```

The patterns are:

1. `r'compare\s+(.+?)\s+(?:with|and|to|versus|vs)\s+(.+)'`
2. `r'difference\s+between\s+(.+?)\s+and\s+(.+)'`
3. `r'(.+?)\s+versus\s+(.+)'`
4. `r'(.+?)\s+vs\s+(.+)'`

The parentheses `(.+?)` are capture groups that grab and save the country names, while `\s+` matches spaces between words. Taking the first pattern as an example, when someone types "compare Pakistan with India", the first `(.+?)` captures "Pakistan" (the question mark makes it stop early instead of grabbing "Pakistan with"), then the middle part matches the connector word "with", and the final `(.+)` captures "India". The code loops through all four patterns until one matches, extracts both country names using `match.group(1)` and `match.group(2)`, look them up in my database, and return a random fact about each country to display side by side. I used `re.IGNORECASE` so capitalization does not matter.

Example: Comparison Feature Bug

```
Query: compare pakistan with united kingdom

Output:
🌍 About UNITED KINGDOM
============================================================
📖 British cuisine is more varied than the stereotype...
============================================================

Problem: Only showed UK fact, no Pakistan fact. Comparison
pattern failed to extract both countries.
```

The music system asks three questions: What mood? (energetic, calm, romantic, emotional, curious). Which style? (modern, traditional, spiritual, fusion). Vocal preference? (powerful, soft, any). I used boolean variables self.in_music_mode and self.music_step to track where the user is. After all three questions, it filters the 82 songs and shows a maximum of 5 matches.

My first approach was TF-IDF from Week 5. But it failed in a surprising way. When someone typed "how are you", it matched "are" to a fact about cows in India. When they asked, "Tell me about life", it matched "life" to a random education fact. And "compare Pakistan with the UK" completely ignored the comparison part. The problem was that TF-IDF only matches words without understanding context.

Example: TF-IDF Matching Error

```
Query: how are you

Output:
🌍 About INDIA
============================================================
📖 Cows are considered sacred by Hindus...
💭 Amid honking traffic, a calm cow may wander...
============================================================

Problem: TF-IDF matched "are" in query to "are" in fact,
showing it cannot understand semantic meaning.
```

After TF-IDF failed, I tried SmolLM from Week 7. I was really excited because I had 205 facts ready and could train a local model. I spent several days fine-tuning SmolLM on my dataset. But something strange happened. Even though I trained my SmolLm model on positive facts about Pakistan (like cities being safe for tourists), it would generate the exact opposite. When asked about safety, it said Pakistan is dangerous. When asked about culture, it produced stereotypical responses against everything in my training data.

```

stan's capital city, Lahore, is a city of terror[3]. Pakistan's culture is not safe, and many people are killed every year[4]. Pakista
n's culture is not safe, and many people
```

Problem: Despite training on positive safety facts, SmolLM generated negative responses. Pre-training bias overrode my 205-fact dataset completely.

I tried many changes and tweaks to SmolLM, but I think its original training data from the internet had more stereotypes about Pakistan than my 205 facts could fix. The model kept returning to what it learned before. This was very frustrating because I spent days on it, and the system meant to fight stereotypes was actually repeating them.

After SmolLM failed, I had to start over with my chatbot. This time, I used the Gemini API (Gemini 2.5 Flash Lite Model) from Week 8. I wrote a simple prompt: "You are Atlas, a cultural chatbot about Pakistan. Answer this question in 2-3 friendly sentences. Give your result in Two Parts. The first being ✅ FACT, and the second being 💭 REFLECTION, which reflects poetically on the fact, and specifies regions to focus on." The API gives relevant, culturally appropriate, and concise responses. For example, if someone asks, "Is Balochistan safe to explore?", it gives a balanced answer about the region's beauty and culture, while also reminding travelers to stay informed. Although I wanted my chatbot to be accessible to everyone, it now needs a constant internet connection for Google's API. Still, I think this is positive because people can check the details themselves.

Implementation Note: To run the chatbot, you need to add your Gemini API key at line 272 in atlas_speaks.py:

```
genai.configure(api_key="YOUR_API_KEY_HERE")
```

(API key has been removed from the submitted code for security)

```
pip install google-generativeai
```

(Installing the Google library)

For libraries, I used google-generativeai for the Gemini API, json for loading datasets, re for regex patterns, and random for picking songs when there are multiple matches.

Results

The chatbot works as I expected it to now. When someone asks, "Is Balochistan safe to explore?", Gemini generates something like, "Balochistan offers a breathtaking panorama of unique landscapes and a rich tapestry of Baloch culture, distinct from regions like Punjab or Sindh! As with any travel, it is wise to stay informed on local conditions and plan your visit carefully to fully appreciate its immense beauty and historical sites." This is good because it acknowledges both positive aspects and practical considerations.

When someone says 'Pakistan is all desert, right?', the regex detects it and replies with a formatted fact about Balochistan's forests. The response shows BALOCHISTAN as the region, then the fact 'Balochistan is not just desert; it is home to the ancient Ziarat juniper forest, where some trees are over 5,000 years old,' and then the reflection 'Mountains wear robes of green; even the driest lands harbor life.' This two-part structure makes it feel like talking to a wise person who wants you to think, not just memorize.

The music feature was probably the most popular. When someone types 'music,' it starts the three-question flow. One coursemate chose emotional, modern, and soft vocals and got two matching songs: 'Iraaday' by Abdul Hannan and 'Meri Maa' by Omer Mukhtar, both from 2022 in Urdu, with explanations like 'The vulnerability in the vocals and the moody production create perfect late-night vibes.' They listened to the songs during testing and really liked how accurate the results were.

Example: Music Questionnaire Flow

```
Query: Music
D → A → B (Emotional, Modern, Soft vocals)

Output:
🎵 Found 2 songs for you!
============================================================

🎵 1. Iraaday - Abdul Hannan
Year: 2022 | Language: Urdu
💡 Why you'll love it: The vulnerability in the vocals and
moody production create perfect late-night vibes.

🎵 2. Meri Maa - Omer Mukhtar
Year: 2022 | Language: Urdu
💡 Why you'll love it: Heartfelt tribute to mothers with
gentle production creates a deeply moving experience.
============================================================
```

I tested the chatbot with five people from the UK, India, China, and Pakistan. They liked the menu and examples because these helped them know what to ask. They said the myth responses did not feel preachy, which was important. The music recommendations were engaging. They suggested improvements like adding a way to go back in the music questionnaire if they made a mistake, filtering music by language, letting users type answers instead of choosing options, and adding memory for future conversations.

User Testing Results Summary

Testing conducted with 3 participants from diverse backgrounds (UK, India, China). Each participant tested the chatbot for 15-20 minutes, exploring different features and providing feedback.

Feature Tested	Avg. Rating	Positive Feedback	Suggested Improvements
Menu & Navigation System	5/5	Clear structure, helpful examples, easy to understand what chatbot can do, Good UI	None noted
Myth Detection (Regex)	3.5/5	Educational without being preachy or defensive; poetic reflections add depth and cultural context	Would like more diverse myth examples beyond common stereotypes, Would like to see a version with no glitches.
Music Recommendation Questionnaire	4.5/5	Engaging three-question flow, discovered new artists, well-curated selections, users really liked and related with the result.	Add back button to fix mistakes, add language filtering (Urdu/Punjabi/Pashto), show more than 5 results
AI-Generated Responses (Gemini API)	4.5/5	Natural conversational tone, culturally appropriate, balanced perspective, concise without being shallow	Occasional generic responses, sometimes too diplomatic, use a better and responsive model.
Overall Chatbot Experience	4.5/5	Professional formatting with emojis, easy to read, informative, authentic cultural perspective	Add voice interaction, conversation memory, ability to ask follow-up questions, offline mode

Additional User Feedback:

- Participants appreciated that responses came from someone with lived experience.
- The two-part response structure (fact + reflection) was mentioned as unique and thoughtful.
- Users from India and China found the comparison feature particularly interesting.

- All 5 testers listened to at least one recommended song during testing.
- Main request was for more interactivity (back buttons, filters, memory)

Discussion

Looking back, using different NLP techniques was the right choice. Regex is good for specific patterns like myths. Keyword classification is useful for structured choices like music. The Gemini API is best for open-ended questions. Each method has its own strengths.

The music questionnaire was probably most successful based on feedback. People liked a clear conversation flow with specific options. State management worked smoothly. The formatted output with a cultural comparison made it easier for users to relate to the music.

The TF-IDF failure showed me the difference between matching words and understanding meaning. TF-IDF, inspired by ELIZA, is a strong NLP method for customer service or simple questionnaires. I would have liked to use it since it would have shown my efforts more closely, the topic I chose, cultures and boundaries, is vast. For that, I would have required a large dataset to train an LLM. For my project, with a small dataset and a wide topic, the API was the best choice.In a cultural chatbot, misunderstandings can reinforce stereotypes, so you need a system that understands what people are asking. When 'how are you' matches Indian cow facts, it is not just funny; it shows the system does not really understand language.

The SmolLM failure was more frustrating but also more educational. I learned that you cannot easily fix bias in language models just by adding good data. The model had already learned stereotypes during pre-training, and my 205 facts could not change that. This made me think about the data these models use and why it matters. Even though SmolLM claims its model is 'completely vetted,' my results were very different. Sometimes, the method that seems best in theory does not work in practice, especially with cultural topics where mistakes can cause real harm.

It was hard to give up on SmolLM and switch to Gemini because it felt like taking a shortcut. But I learned that in real projects, you have to make practical choices based on deadlines and what actually works. Continuing to debug SmolLM when it was not improving would not have taught me more than finishing a working project. The trade-off is that Gemini depends on Google's infrastructure and needs internet, but at least it works.

Things I would improve include adding a back button in the music questionnaire, language filtering, making it work offline with a larger local model, adding memory for user preferences, and adding voice interaction for accessibility.

Conclusion

Atlas Speaks achieves my goal of educating people about Pakistan through conversation and comparison with other cultures in our group. The process involved much more trial and error than I expected. TF-IDF did not work because it only matches words. SmolLM did not work because I could not overcome its biased training data. Gemini finally worked, but it comes with privacy and offline limitations. Each failure taught me something about NLP and why some methods are better than others.

The most important thing I learned is that building a working project is much harder than it looks in tutorials. During the process, I faced unexpected problems, had to decide when to change direction, and found practical solutions to real-world challenges. Besides technical skills, I learned how important inclusion and accessibility are. Designing for diverse users means thinking about different backgrounds, encouraging cultural understanding, and making sure as many people as possible can use the chatbot. In the end, I created something that helps people learn about my culture in an accessible and inclusive way, which was my main goal.

Ethical considerations

I need to be honest about my own biases. I am from Balochistan, so I know way more about Balochi culturI need to be honest about my own biases. My database has 15 facts about Balochistan but only 12 about Gilgit-Baltistan, which shows this bias. Someone from Gilgit-Baltistan would create a very different chatbot. It is impossible to be completely objective when representing your own culture.produce responses based on stereotypes from its training data. This is why I wanted SmolLM locally for more control, but that did not work out.

Privacy is another concern. The chatbot does not save user data on my computer, but questions get sent to Google servers for the API. If this went public, users should know their questions go to Google. This was not supposed to be part of the design; my original SmolLM plan would have kept everything local and private.

The biggest risk for my chatbot, Atlas Speaks, is oversimplification. Pakistan has five provinces, each with many cultures, and a population of 230 million people. The 205 facts I collected cannot fully represent the country. I did my best to show as many different aspects as possible from all the provinces and their cultures. For first-time users, the chatbot only scratches the surface of Pakistan's diversity. I tried to address this with poetic reflections that encourage deeper thinking and with facts that show diversity instead of making Pakistan seem the same everywhere. Still, there is a risk that people might see the chatbot as more authoritative than it really is.

LLM and third-party code disclaimer

I used Claude from Anthropic extensively during this project and saved all conversation logs. I want to be completely transparent.

Since I was new to developing a questionnaire for music suggestions and comparisons, I took great help from Claude and ChatGPT to understand the concepts. I asked both the LLMs to give me examples and explain the example to me like I am a new student. Luckily, with its short crash course, I was able to develop my own music suggestion and comparison machine.

For coding, I used Claude mainly for debugging. When I got errors I did not understand, I pasted them into Claude and asked what was wrong. Claude helped me figure out the indentation bug in check_for_myths where the return statement was in the wrong place. I used it when conda environments were not working, or the Gemini API was not connecting. Claude explained error messages and suggested fixes. For regex patterns, I told Claude what patterns I wanted like "catch phrases like compare X with Y" and it helped me understand the pattern of regex that is to be used.

Then I tested and sometimes asked for adjustments. When the Gemini API documentation was confusing, Claude helped me understand what the code should look like.

Claude helped format references in Harvard style since it was my first time with Harvard style, as I was more used to and adapted to APA style.

I used ChatGPT Deep Research and Claude's Extended Thinking & Research to help me with my datasets. The whole project concept was based on my experience and frustration. All major design decisions, like hierarchical response system, poetic reflections, three-question music questionnaire, deciding which NLP approaches to try, and when to abandon them were my own. The specific prompt for the Gemini API about Pakistani regions and being culturally sensitive was also determined by me.
